

S.A. Wright et al. analysed a CO<sub>2</sub>-CB integrated with an sCO<sub>2</sub> waste heat recovery plant. In the charging cycle, energy was stored as ice, produced by the trans -critical CO<sub>2</sub> heat pump/refrigeration cycle at -5 °C; while on peak demand period, that ice is melted during the discharge.

The efficient methods (like batteries, pumped storage, and flywheels) retrieve 90% of the energy, but are very limited in terms of how much energy they can store. The large-scale methods (like chemical storage) can store virtually unlimited amounts of energy but are very inefficient (75% losses). Nothing is simultaneously efficient and large-scale.

Large-scale energy storage technologies mainly contain both physical energy storage technologies (e.g., hydro-pumping, compressed-air, fly wheel, superconductor, and super-capacity), and chemical energy storage technologies (e.g., flow batteries, sodium-sulfur batteries, lithium-ion batteries, and lead batteries).
