It is due to increased distributed generation in distribution system resulting in bi-directional power flow and operation scenarios variance. It is considered that the flexibility in a power system is "consumed" by load changes, weather forecast errors, generation units or transmission line outages, and generation from variable RES [ 21 ].

Optimal reactive power dispatch (ORPD) is a complex and non-linear problem, and is one of the sub-problems of optimal power flow (OPF) in a power system. ORPD is formulated as a single-objective problem to minimize the active power loss in a transmission system. The effects of distributed generation are: short circuit levels are increased, load losses change, voltage profiles change along the network, voltage transients will appear, congestions can appear in system branches, power quality and reliability may be affected and the networks protections may not function properly.

The optimal power factor setting for each distributed generation source was dynamically adjusted during real-time power grid operation, resulting in further minimisation of the system loss reduction. The overall loss reduction achieved was 96.04% relative to the base case of no distributed generation connection.
