Solar cells had a power conversion efficiency of more than 25%, and they retained more than 95% of efficiency after 2000 hours of maximum power point operations at 65°C. --Phil Szuromi Robust contact schemes that boost stability and simplify the production process are needed for perovskite solar cells (PSCs).

Organic hole transport layers (HTLs) have been known to be susceptible to thermal stress, leading to poor long-term stability in perovskite solar cells (PSCs). We synthesized three 2,5-dialkoxy-substituted, 1,4-bis(2-thienyl)phenylene (TPT)-based conjugated polymers (CPs) linked with thiophene-based (thiophene (T) and thienothiophene (TT)) comonomers and ...

Although, in this case, the presence of PbI₂ caused only a slight reduction in device performance. Multiple reports have monitored the thermal stability of the perovskite under vacuum conditions. As previously

mentioned, Philippe et al. observed the decomposition of the perovskite film after heating at 100 °C.

With a record efficiency above 25%, the main hurdle for the commercialization of perovskite solar cells (PSCs) is their long-term operational stability. Although different strategies have been applied, the stability of PSCs is still far below the 25 year requirement demonstrated by commercial photovoltaic technologies.
