The document discusses three types of mechanical energy storage: pumped hydroelectric storage (PHS), compressed air energy storage (CAES), and flywheels. PHS involves pumping water to a higher elevation and releasing it through turbines to generate power. CAES compresses air underground for later use in power generation.

Once the demand for electricity power overcome the available energy supply, the stored energy would be release to meet with the energy demand. Mechanical energy storage can be classified into three major types: Compressed air storage, Flywheel Storage and Pumped Storage.

A flywheel is a rotating mechanical device that is used to store rotational energy that can be called up instantaneously. At the most basic level, a flywheel contains a spinning mass in its center that is driven by a motor - and when energy is needed, the spinning force drives a device similar to a turbine to produce electricity, slowing the rate of rotation.

Pumped thermal energy storage (PTES) is an advanced concept for thermo-mechanical energy storage and has the highest potential for development. While an ideal implementation can reach a storage efficiency of 100%, roundtrip efficiencies in the range between 50% and 70% are expected for technical systems.
