

Operating principle of photovoltaic cell

Photovoltaic Cell Defined: A photovoltaic cell, also known as a solar cell, is defined as a device that converts light into electricity using the photovoltaic effect. **Working Principle:** The solar cell working principle involves converting light energy into electrical energy by separating light-induced charge carriers within a semiconductor.

The principle of operation of photovoltaic cells, the photovoltaic effect, was first observed by French physicist Edmond Becquerel in 1839. He discovered that certain materials would produce small amounts of electric current when exposed to light. This effect is a direct conversion of light energy (photons) into electrical energy by the action ...

The photovoltaic process bears certain similarities to photosynthesis, the process by which the energy in light is converted into chemical energy in plants. Since solar cells obviously cannot produce electric power in the dark, part of the energy they develop under light is stored, in many applications, for use when light is not available.

The solar cell (or circuit) may also contain series (R_s) and parallel (or shunt, R_p) resistances, leading to a characteristic of the form $I = I_0 (e^{qV/kT} - 1) - V/R_p - I_{sc}$. Figure 4 The superposition principle for solar cells. $FF = FF_0(1 - \dots$

Solar cells are the electrical devices that directly convert solar energy (sunlight) into electric energy. This conversion is based on the principle of photovoltaic effect in which DC voltage is generated due to flow of electric current between two layers of semiconducting materials (having opposite conductivities) upon exposure to the sunlight [].

A photovoltaic cell alone cannot produce enough usable electricity for more than a small electronic gadget. Solar cells are wired together and installed on top of a substrate like metal or glass to create solar panels, which are installed in groups to form a solar power system to produce the energy for a home.
