Carbon Bonding. Carbon contains four electrons in its outer shell. Therefore, it can form four covalent bonds with other atoms or molecules. The simplest organic carbon molecule is methane (CH 4), in which four hydrogen atoms bind to a carbon atom (Figure (PageIndex{1})). The organic molecules that store the most energy are called fats or triglycerides. The body uses carbohydrates (glycogen) for medium-term energy storage and lipids (fats or triglycerides) for long-term energy storage. Carbohydrates store about 16 kJ/g, while fats store about 39 kJ/g. Gram for gram, triglycerides store more than twice as much energy as ...

Carbon's affinity for covalent bonding means that many distinct and relatively stable organic molecules nevertheless readily form larger, more complex molecules. Any large molecule is referred to as macromolecule (macro- = "large"), and the organic compounds in this section all fit this description. However, some macromolecules are made ...

Choosing classes of molecules for information storage that offer long-term stability, with no energy required for storage, is one long-term objective of this area of research. Long-term stability of appropriate organic molecules with appropriate structures over hundreds of years has not been systematically explored but is commonly assumed.

lipid, any of a diverse group of organic compounds including fats, oils, hormones, and certain components of membranes that are grouped together because they do not interact appreciably with water. One type of lipid, the triglycerides, is sequestered as fat in adipose cells, which serve as the energy-storage depot for organisms and also provide thermal insulation.
